

Q17. Best time to buy and sell stock.

i/p  $\rightarrow \{7, 1, 5, 3, 6, 4\}$

o/p  $\rightarrow 5 \rightarrow \text{maximum profit } 6 - 1 = 5$

Brute force

Take  $i = 0$  and  $j = i + 1$  and then just find the maximum profit possible.  $j$  here will represent the selling Index &  $i$  represents the buying index and we don't have to care about the thing of first buying & then selling as  $j$  will always be ahead of  $i$ .

Optimal solution + Dry run

$\text{mini} = \text{INT\_MAX}$

$\text{profit} = 0$

1)  $i = 0$

$\text{prices}[i] = 7$

$7 < \text{INT\_MAX} \Rightarrow \text{True}$  & hence  $\text{mini} = 7$

2)  $i = 1$

$\text{prices}[i] = 1$

$1 < 7 \Rightarrow \text{True}$  & hence  $\text{mini} = 1$

3)  $i = 2$

$\text{prices}[i] = 5$

$5 < 1 \Rightarrow \text{False}$  and hence

$\text{profit} = \max(0, 5 - 1) = \max(0, 4) = 4$

$\uparrow \quad \rightarrow \text{mini}$   
 $\text{prices}[i]$

4)  $i = 3$

prices[i] = 3

$3 < 1 \Rightarrow \text{False}$  and hence

profit =  $\max(4, 3-1) = \max(4, 2) = 4$

5)  $i = 4$

prices[i] = 6

$6 < 1 \Rightarrow \text{False}$  and hence

profit =  $\max(4, 6-1) = \max(4, 5) = 5$

6)  $i = 5$

prices[i] = 4

$4 < 1 \Rightarrow \text{False}$  and hence

profit =  $\max(5, 4-1) = \max(5, 3) = 5$

Hence we have now fully traversed the array and the profit comes out to be 5. Simply return profit.

Code

```
int maxProfit(vector<int> & prices){
```

```
    // Setting the initial values
```

```
    int mini = INT_MAX;
```

```
    int profit = 0;
```

```
    // Traverse the whole array
```

```
    for (int i = 0; i < prices.size(); i++) {
```

```
        // Should buy if condition satisfied
```

```
        if (prices[i] < mini) {
```

```
            mini = prices[i];
```

```
        }
```

```
        else { // Should sell
```

```
            profit = max(profit, prices[i] - mini);
```

}

{

return profit;

{

Time complexity =  $O(n)$ Space complexity =  $O(1)$
