Sudoku Solver

There will be a 9×9 matrix.

		I			II			III
		IV			V			VI
		VII			VIII			IX

- * In each column there should be numbers from 1 to 9 & should not be repeating.
- * In each row there should be numbers from 1 to 9 and should not be repeating
- * There will be 9, 3×3 boxes & each box should have numbers from 1 to 9 & there should be no repetition. 9 boxes each of 3×3 have been marked.

All the above 3 conditions are mandatory conditions.

Note - If there are many clues, then less chances of multiple solutions. If there are less clues, then high chance of multiple solution. The exact number of clues is 17 for which unique solution will exist.
↳ or above

	0	1	2	3	4	5	6	7	8
0	4	5							
1			2		7		6	3	
2								2	8
3				9	5				
4		8	6				2		
5		2		6			7	5	
6							4	7	6
7		7			4	5			
8			8			9			

The above is the question & the numbers which are written in black are known as clues.

We will start from cell $s[0][2]$ and apply

isSafe function to place numbers from 1 to 9 starting from 1. In the isSafe function we need to check the 3 conditions which we have already discussed. If a particular number isSafe, simply insert it & move ahead. Suppose we are not able to insert any number & this means that there is fault in previous placement just like n-queen problem. Here backtracking plays an important role. This is the only logic we need to apply until we fill all the cells.

Code

```
bool isSafe (int value, int board[][9],
             int curr_row, int curr_col) {
    // Row check → Same row, changing column
    for (int col = 0; col < 9; col++) {
        if (board[curr_row][col] == value)
            return false;
    }
    // Column check → Same column, changing row
    for (int row = 0; row < 9; row++) {
        if (board[row][curr_col] == value)
            return false;
    }
    // 3x3 box checking
    for (int i = 0; i < 9; i++) {
        if (board[3*(curr_row/3) + i/3][3*(curr_col/3) + i%3] == value) {
            return false;
        }
    }
    return true; // Safe value
}
```

// Tweek done → return type bool to avoid base case

```
bool solve (int board[][9], int n) {
```

// Traversing the sudoku board

```
for (int i=0; i<n; i++) {
```

```
    for (int j=0; j<n; j++) {
```

// Insert only in empty cell

```
        if (board[i][j] == 0) {
```

1 to 9 value ← for (int value = 1; value <= 9; value++) {

Check for safety ← if (isSafe (value, board, i, j) {

If safe, insert ← board[i][j] = value;

// Recursive call

```
        bool aage Solution = solve (board, n);
```

// Found solution or not?

// Due to below line, we don't need base case

```
        if (aage Solution) {
```

Don't explore further ← return true; // Found solⁿ as in question }

it says unique

// Backtracking

solⁿ is there.

```
        board[i][j] = 0;
```

```
    }
```

```
}
```

```
    return false; // If no value from 1 to 9 can be inserted.
```

```
}
```

```
}
```

```
}
```

```
return true; // All cells are filled & hence return true
```

In the main function simply print the sudoku board as the values will be filled.

Understanding 3x3 box check condition

* $i = 0 \text{ to } 8$

→ sent in isSafe ←

board $[3 * (\text{curr-row}/3) + i/3][3 * (\text{curr-col}/3) + i\%3]$

	0	1	2
0	4	5	
1			2
2			

→ (curr-row, curr-col) → (0, 2)

* $i = 0$

board $[3 * (0/3) + 0/3][3 * (2/3) + 0\%3]$

board $[0 + 0][3 * (0) + 0] \Rightarrow \text{board}[0][0]$

* $i = 1$

board $[3 * (0/3) + 1/3][3 * (2/3) + 1\%3]$

board $[0][0 + 1] \Rightarrow \text{board}[0][1]$

* $i = 2$

board $[3 * (0/3) + 2/3][3 * (2/3) + 2\%3]$

board $[0 + 0][0 + 2] \Rightarrow \text{board}[0][2]$

* $i = 3$

board $[3 * (0/3) + 3/3][3 * (2/3) + 3\%3]$

board $[0 + 1][0 + 0] \Rightarrow \text{board}[1][0]$

* $i = 4$

board $[3 * (0/3) + 4/3][3 * (2/3) + 4\%3]$

board $[0 + 1][0 + 1] \Rightarrow \text{board}[1][1]$

* $i = 5$

board $[3 * (0/3) + 5/3][3 * (2/3) + 5\%3]$

board $[0 + 1][0 + 2] \Rightarrow \text{board}[1][2]$

* $i = 6$

board $[3 * (0/3) + 6/3][3 * (2/3) + 6\%3]$

board $[0 + 2][0 + 0] \Rightarrow \text{board}[2][0]$

* $i = 7$

board $[3 * (0/3) + 7/3][3 * (2/3) + 7\%3]$

board $[0 + 2][0 + 1] \Rightarrow \text{board}[2][1]$

* $i = 8$

$\text{board}[3 * (0/3) + 8/3][3 * (2/3) + 8\%3]$

$\text{board}[0+2][0+2] \Rightarrow \text{board}[2][2]$

Note $\rightarrow 3 * (\text{curr_row}/3) \rightarrow$ Starting row of each box
 $i/3 \rightarrow$ movement in down direxn
 $3 * (\text{curr_col}/3) \rightarrow$ starting col of each box
 $i\%3 \rightarrow$ movement in right direxn
