Basic Maths In interview the coding questions are purely based on maths & by these concepts, we can

find the optimal solution.

- (i) Prime number

 There can be multiple approaches to find whether

 a given number is prime or not.
 - Naive approach => Check for divisibility of the number from I to number itself & if it has exactly 2 factors, then we say the number is a prime.
- * I is not a prime as it does not have a factors.

 * 2 is the smallest prime number as it has I &
 2 as factor.

There are other approaches such as the square root approach, sieve of Eratosthenes, segmented

sieve .

Q+ Count the number of primes strictly less than n.

> $i/b \rightarrow 5$ $0/b \rightarrow 2 \rightarrow (2,3)$

Naive approach $TC = O(n^2)$ Ryn a loop from i = 2 to n & check Whether i is prime or not. If we find that i is a prime number, then increment the count value & return count after the end of for loop.

Qde

bool is Prime (int n) {

if (n = 0 1 | n = 1)

return false i

for (int i = 2 ; i < n; i++) {

if (n°/. i = =0)

return false;

return true;

int count Prime (int n) {

int count = 0;

for (int i=2; i<n; i++){

if (is Prime (i))

count ++1

return counti

When we try to submit this on leet code, it will give TLE as the above solution have time complexity as $O(n^2)$ as in the function named is Prime there is one for loop & this function is called in the another for loop & due to this, we obtain the nested for loops.

Better abbroach We have to improve the is Prime function but how can we do it? The loop inside is Prime function is running from i=2 to i<1, so can we reduce it? Let's assume n is non-prime

1,2,3---, n-1, n

4) at least have I factor as we have assumed n is not brime.

This means we can say they (the number) has 2 factors a & b $n = a \times b$

 $\frac{a>\sqrt{\pi}}{b>\sqrt{\pi}}$ $\frac{3}{3}$ $\frac{ab>\pi}{ab>\pi}$

But this is not possible & hence we can conclude that atleast one of the factor must be less than In. This is not possible as ab=n.

Of we can't find any factor less than In, & this means n is prime. So we can reduce the for loop inside is Prime to Tr.

But if we modify the for loop inside is Prime, still we won't be able to submit as still the time complexity is too high.

Modification TC = 0 (n m)

bool is Prime (int n) {

if(n < = 1)

return false:

 $for (int i = 0) i < = sqrt(n) ; i++){}$ if (n% i = = 0)

3 Atleast one factor should be less return true; than In to be non-prime.

Better Approach-2 Here we will be using the concept of Sieve of Eratosthenes theorm. This is used when we want to find the total Count of primes less than n.

Suppose that n=21. So make an away consisting of numbers 2 to 20 & initially we assume that all of them are primed hence we mark all of them true.

2 3 4 5 6 7 8 9 10 11 12 13

*	Now 2 is a prime number & when we
	start reading the table of 2, all of them
	will be non-prime-Somark 4,6,8,10,12,
	14, 16, 18, 20 as false i.e non-prime.

* Now 3 is a prime number & hence mark 6, 9, 12, 15, 18 as false i'e non-prime.

* Now we go to 4 & we get to know it is already non-prime so move ahead.

* Now we go to 5 & then mark 10, 15, 20 as false i'e non-prime

So by the above dry run we need to mark the multiples of all prime as non-prime.

$2 \rightarrow T$	17 -) T
	18 -> F
	19 -> T
$\begin{array}{cccccccccccccccccccccccccccccccccccc$	$20 \rightarrow \bigcirc$
$5 \rightarrow T$	

7 -1 -

10 -> F

11 -

12 -> F

 $13 \rightarrow T$

14 - F

15 -> F

16 -> F

Now just count all the T& return that number.

Int count Primes (int n) 2

if (n = = 0)

return oi

Vector < bool> prime (no true);

prime [0] = prime [1] = false i int count = 0;

for (int i=2; i<n; i++) {

If (prime (i)) {

count ++ j

int 1=2* L'j

mark the while (j < n) {

multiples of prime [j] = false j prime as

1°=1+1)

non-prime

return count i

Segmented Sieve

It is simply the variation of Sieve of Eratosthenes in which we have been given a range I to h & in this range we have to count the no. of primes.

Time complexity of Sieve of Exatosthenes = O(nlog(logn))

Note + The averay which we have made is known as Sieve.

 $\frac{TC \rightarrow n \times / n + h + n + n + n}{2}$

Harmonic Progression Take n of prime numbers out Tailor servies

GCD/HCF GCD is the Greatest Common Divisor. HCF is highest common factor.

24,72

a % hcf = 0 b % hcf = 0

24 = 1 x 2 x 2 x 2 x 3 72 = 1 x 3 x 2 x 2 x 3 x 3.

hcf = 2x2x2x3 = 24

I maximum

Euclid's Algorithm

gcd (a,b) = gcd (a-b,b) a> b

gcd (a,b) = gcd (b-a,a) 9<6

Also gcd (a,b) = gcd (a%b,b) a>b But we will be using the - operation as % is the heavy operation.

Ex. 9 cd (72, 24)

gcd (48,24) gcd (24,24) gcd (0,24) 4 Ans

We have to apply the above formulae until any one of the parameter becomes

int gcd (int a, int b) { //Base Case

if $(\alpha = -0)$

return bi

if (b = = 0)

return ai

While (a >0 & & b >0) { 1/Run loop until any of parameter becomes 0

a = a - bj

else

b = b - ai

if (a = = 0)

return bi

else

return a j

If we have found the hof, then we can simply find lom also.

lcm (a,b) * hcf (a,b) = a* b

However we can prove the Euclid's algorithm via mathematical induction but we don't have to deep dive.

Modulo Arithemetic a%n, then the answer will lie blue o to n-1 where o & n-1 are inclusive

$$10\%3 \Rightarrow ans = [0,1,2,3]$$

Properties of modulo
These properties will be used to handle the
cases of overflow-as it might happen sometimes
that it can't get stored in a farticular
data type, so we basically apply modulo
operation.

4) a% m * b% m = (a*b)% m We need to remember the above 4 properties to solve the coding problems in a better way.

Fast Exponentiation Suppose that we want to find 210, then multiply 2, 10 times with each other. 210 => 2×2×---×2

10 times

normal soin to find a'b will be O(b)

The method is that

ans = 1

 $for (int i = 1 ; i < = 10 ; i + +) {$

 2^{10} ans = ans # 2j

3

cout << ans ;

This is also known as slow exponentiation.

Code of slow exponentiation

int power (int a, int b) {

int ans = 1;

for (int i=1; i<=b; i++){

 a^b ans = ans *

4

return ans;

3

Time complexity = 0(b)

We use the fast exponentiation method to avoid any TLE errors. This method has complexity as O(logb)

a ^ b

(1) b = even

$$2^{10} \Rightarrow (2^{5})^{2}$$

(ii) b
$$\Rightarrow$$
 odd $a^b = (a^{b/2})^2$. a

$$211 \Rightarrow (25)^2 \cdot 2$$

We see how we are dividing. This is basically known as divide & conquer approach.

Code of Fast exponentiation

$$a = a * a :$$
 $b = b > 1 :$

return ansi

$$Q = 5 \times 5 = 25$$

 $b = 4 > 1 = 2$

a)
$$a = 25$$
, $b = 2$, ans = 1

$$a = asxas = 6as$$

3)
$$a = 625$$
, $b = 1$, ans=1

$$ans = 1 \times 625 = 625$$

Example
$$a = 2$$
, $b = 5$, ans $= 1$

$$b \Rightarrow odd$$

$$ans = Ixa = 2$$

$$b = 5 >> 1 = 2$$

 $a = a \times a = 2 \times 2 = 4$

$$a = 4x4 = 016$$

3)
$$b = 1, a = 16, ans = 2$$

$$ans = 2 \times 16 = 32$$

$$a = 16 \times 16 = 256$$

Hence exit the while loop & return ans which is 32.

Q-1 Modular exponentiation for large numbers.
(ocr) %. m

$$i/p \rightarrow x = 3$$
, $n = 2$, $m = 4$
 $o/p \rightarrow 1$ as $(3^2) \% 4 = 9\% 4 = 1$

<u>Code</u>

It is important to note that it is always safe to do mod if we might get a very large number.

long long int pow Mod (long long int x, long long int r, long long int m) {

long long int ans = 1 j

While (n >0) {
if (n &1) {

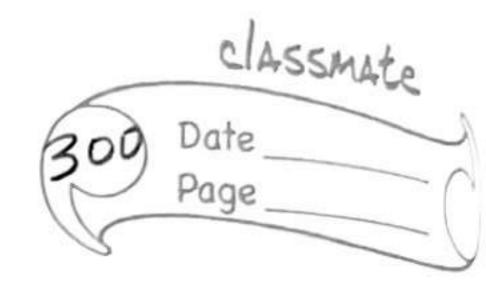

ans = (ans *xx) % m) // May :
be a bigger no out :

J DC = (x xx)% m ; 06 ronge

n = n >>1

return (ans % m)

z
